Augeas – a configuration API

David Lutterkort
Red Hat, Inc.

Configuration Management

Sitewide configuration

Local configuration

Editing of Configuration Data

(1) Keyhole approaches

(2) Greenfield approaches

(3) Templating

Missing pieces

- Handle configuration data uniformly
- Policy/delegation
- Remotable API

Augeas lays the foundation for addressing these

Design Goals

(1) Deal with configuration data in its current place

Design Goals

(2) Expose abstract tree view of configuration data

Design Goals

(3) Preserve “unimportant” detail

Design Goals

(4) Describe new file formats easily and safely

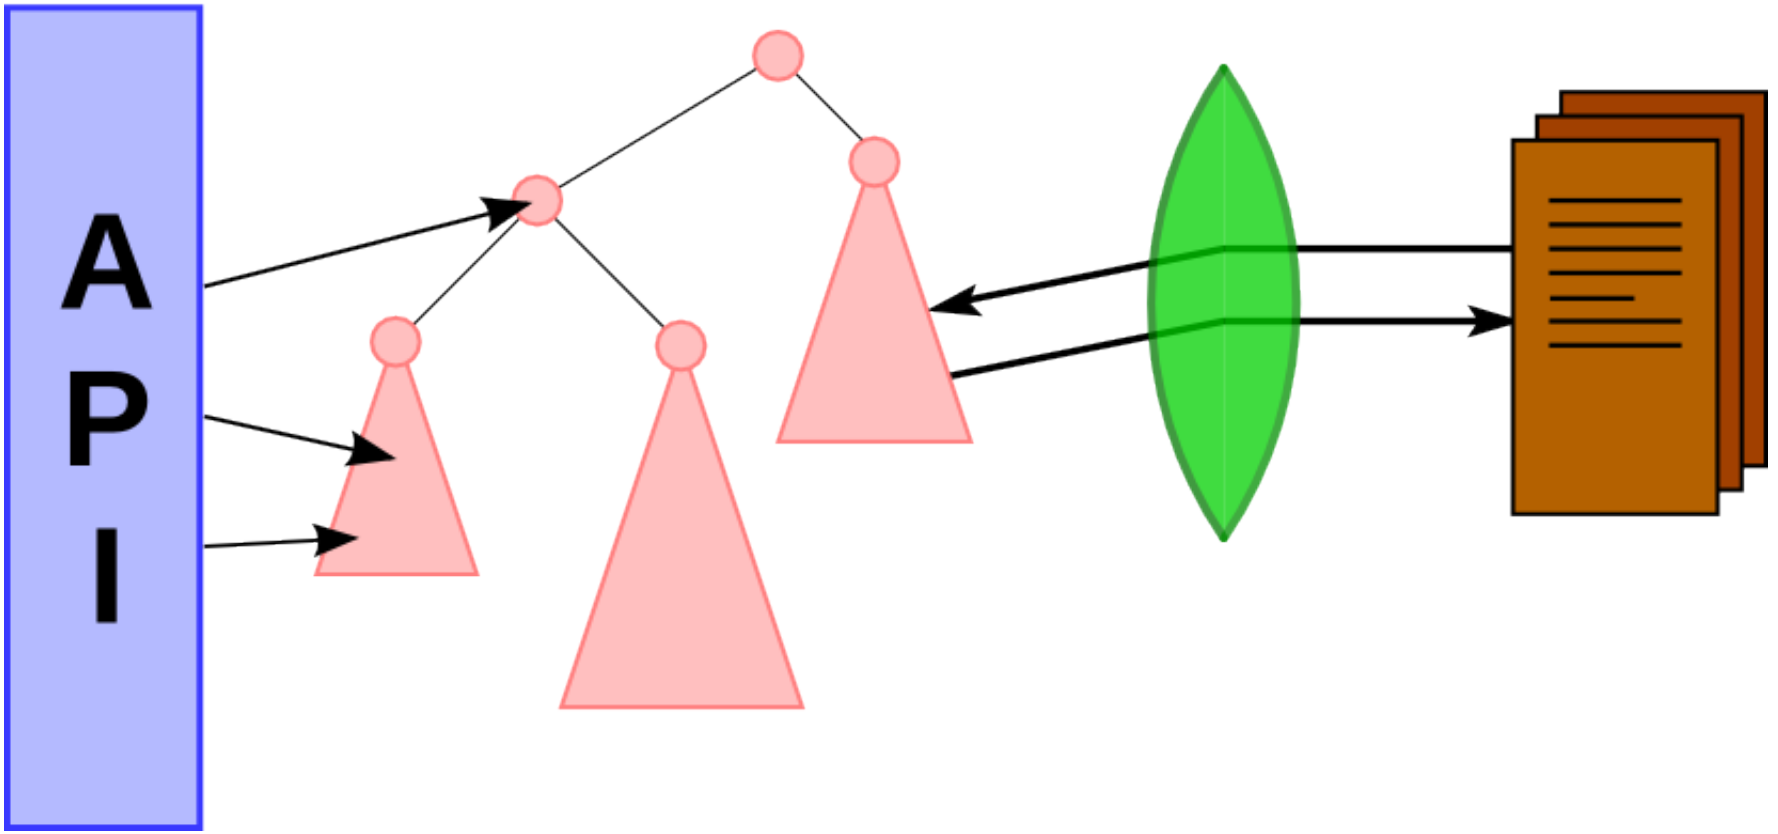
Design Goals

(5) Language neutral implementation

Design Goals

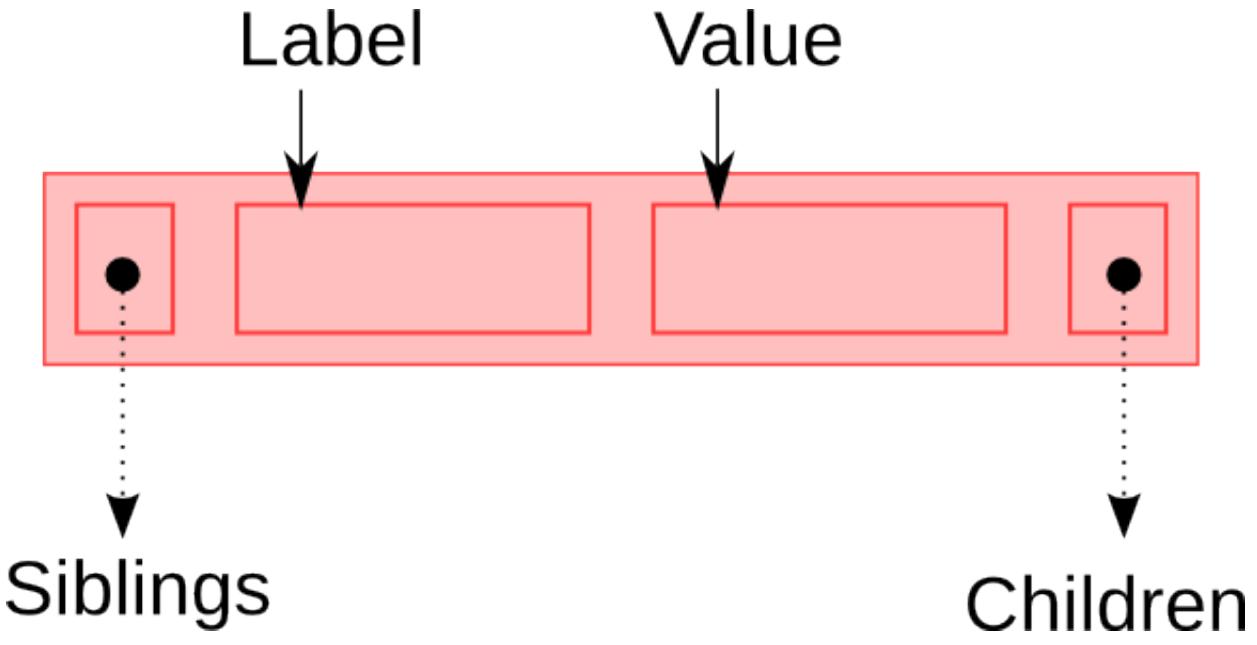
(6) Focus on configuration editing

Overall architecture



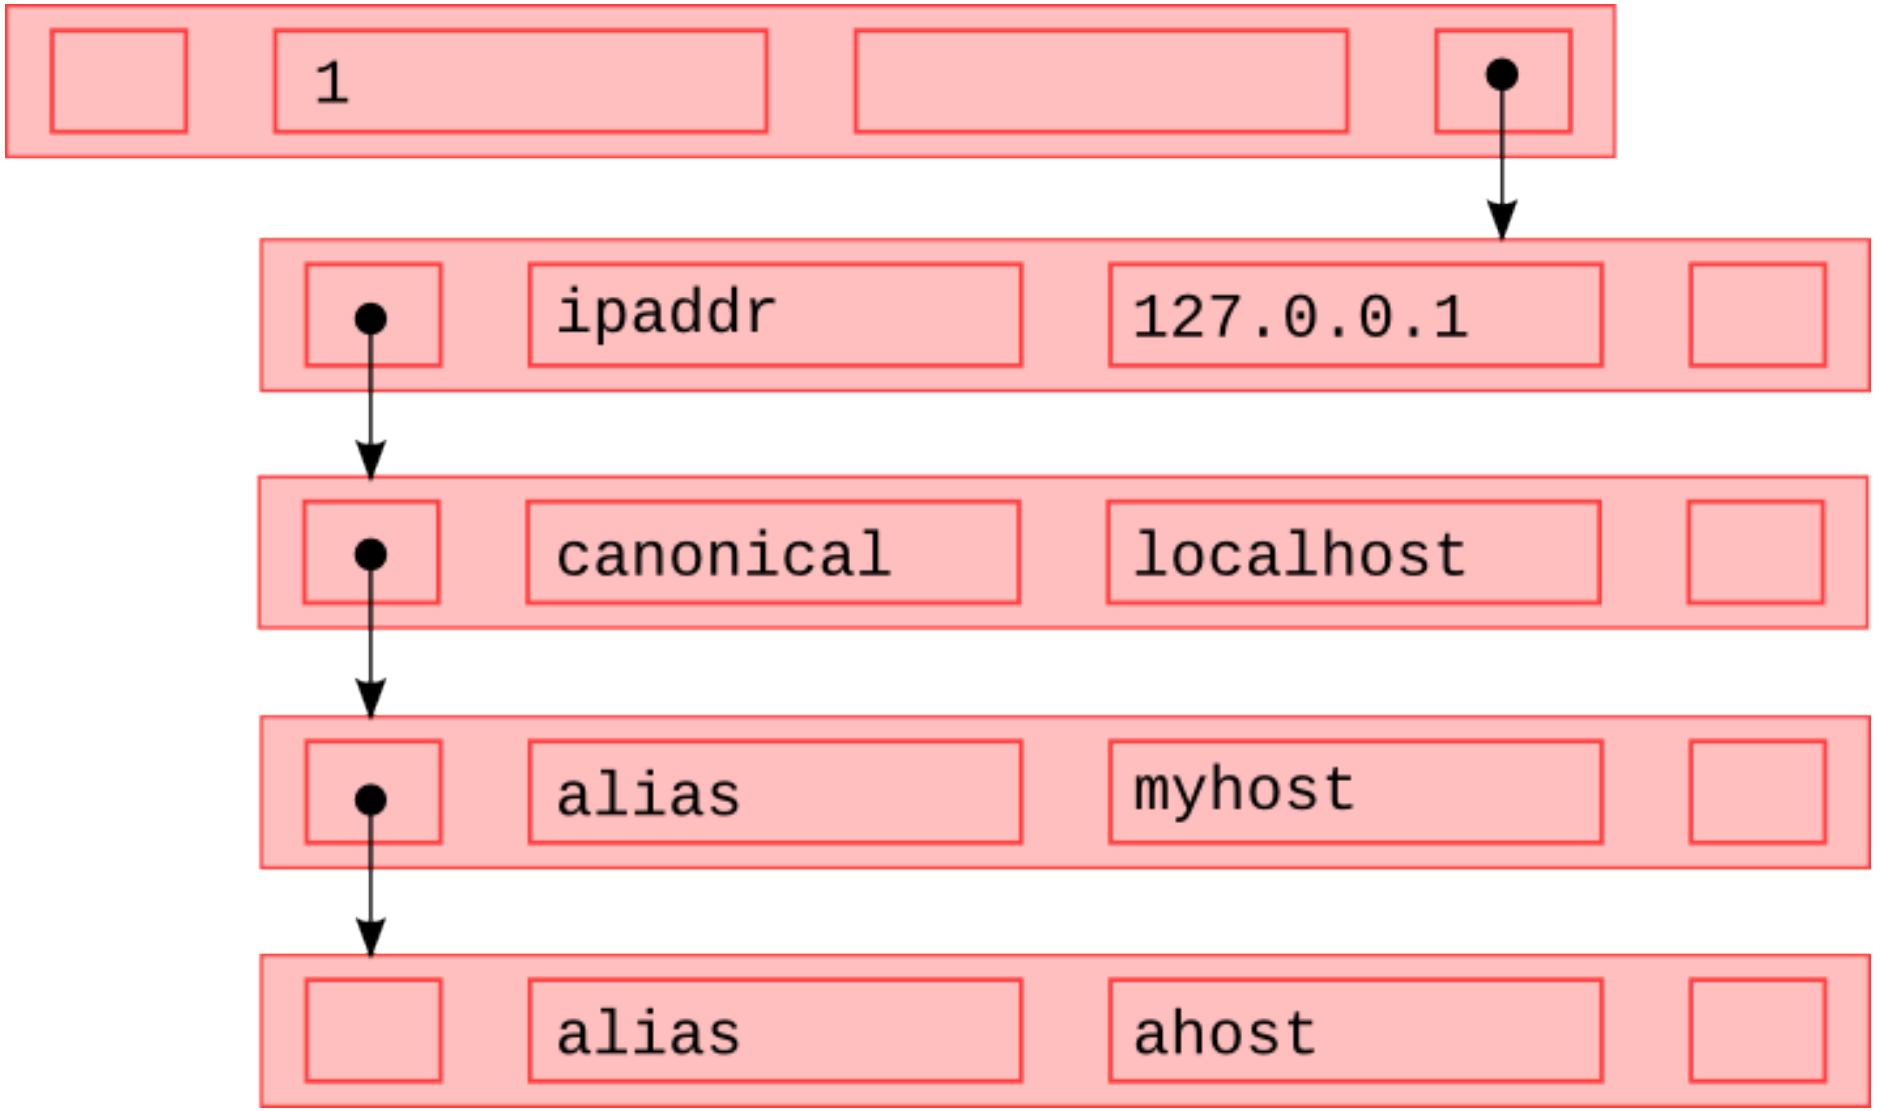
Augeas

The Augeas Tree



Augeas

The Augeas Tree



Augeas

The public Augeas API

- Small number of calls to modify tree
  - ***init/close***
  - ***get/set*** value associated with a node
  - ***match*** nodes with path expression
  - ***insert*** before/after existing node
  - ***rm*** subtree
  - ***save*** tree back to file
- Possible additions
  - copy/move subtrees
  - load specific files

Augeas

The public Augeas API

C API (`libaugeas.so`)

Command line tool `augtool`

Language bindings for Python, Ruby, Ocaml, Perl, Java, ...

Example: **/etc/hosts**

Format:

```
# ipaddr □ canonical (□ alias)* \n
127.0.0.1 □ localhost □ localhost.localdomain □ host.domain
```

Schema:

```
/files/etc/hosts
                    1/
                     ipaddr = 127.0.0.1
                     canonical = localhost
                     alias = localhost.localdomain
                     alias = host.domain
```

Augeas

Example: **/etc/hosts**

```
augtool> set /files/etc/hosts/1/alias[2] myhost.domain
```

Schema:

```
/files/etc/hosts
                  1/
                   ipaddr = 127.0.0.1
                   canonical = localhost
                   alias = localhost.localdomain
                   alias = myhost.domain
```

Example: **/etc/hosts**

```
augtool> ins alias after /files/etc/hosts/1/alias[1]
```

Schema:

```
/files/etc/hosts
                  1/
                   ipaddr = 127.0.0.1
                   canonical = localhost
                   alias = localhost.localdomain
                   alias
                   alias = myhost.domain
```

Augeas

Example: **/etc/hosts**

```
augtool> set /files/etc/hosts/1/alias[2] myhost
```

Schema:

```
/files/etc/hosts
                  1/
                   ipaddr = 127.0.0.1
                   canonical = localhost
                   alias = localhost.localdomain
                   alias = myhost
                   alias = myhost.domain
```

Augeas

Example: **/etc/hosts**

```
augtool> save
```

New `/etc/hosts`:

```
# ipaddr □ canonical (□ alias)* \n
127.0.0.1 □ localhost □ localhost.localdomain □ myhost □
  myhost.domain
```

Augeas

Example: yum configuration

Trees underneath

```
/files/etc/yum.conf
/files/etc/yum.repos.d/some.repo
```

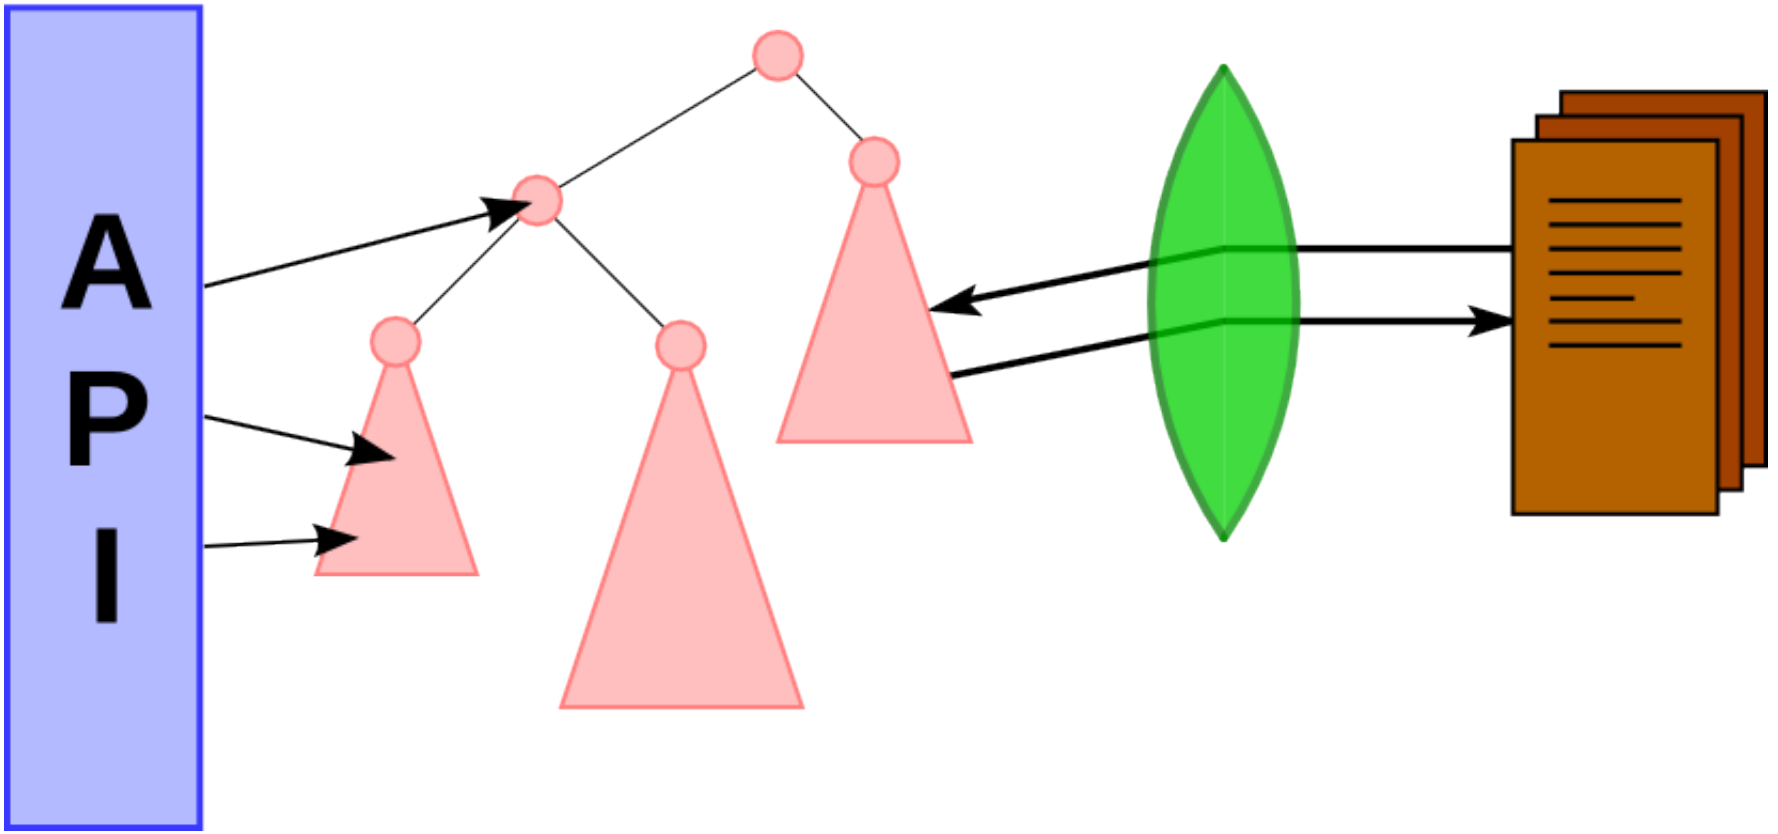
Schema

```
/section/key = value
```

Switch Fedora repo to internal mirror:

```
R=/files/etc/yum.repos.d/fedora.repo
augtool> rm $R/fedora/mirrorlist
augtool> set $R/fedora/baseurl mirror1
augtool> ins baseurl after $R/fedora/baseurl
augtool> set $R/fedora/baseurl[last()] mirror2
```

Overall architecture



Augeas

Example: hosts.aug

```
module Hosts =
  autoload xfm

  let ws = del /[ \t]+/ " "
  let eol = del "\n" "\n"

  let comment = [ del /(#.*|[ \t]*)\n/ "\n" ]

  let word = /[^# \n\t]+/

  let record =
   [ seq "host" . [ label "ipaddr" . store word ] .
             ws . [ label "canonical" . store word ] .
                  [ label "alias" . ws . store word ]* .
     eol ]

  let lns = ( comment | record ) *

  let xfm = transform lns (incl "/etc/hosts")
```

Augeas

Schema description

```
module Yum =
  autoload xfm

  let lns = ...

  let filter = (incl "/etc/yum.conf")
             . (incl "/etc/yum.repos.d/*")
             . Util.stdexcl

  let xfm = transform lns filter
```

Augeas

Schema description

```
module Yum =
  autoload xfm

  let lns = ...

  let filter = (incl "/etc/yum.conf")
             . (incl "/etc/yum.repos.d/*")
             . Util.stdexcl

  let xfm = transform lns filter
```

Augeas

Schema description

```
module Yum =
  autoload xfm

  let lns = ...

  let filter = (incl "/etc/yum.conf")
             . (incl "/etc/yum.repos.d/*")
             . Util.stdexcl

  let xfm = transform lns filter
```

Augeas

Schema description

```
module Yum =
  autoload xfm

  let lns = ...

  let filter = (incl "/etc/yum.conf")
             . (incl "/etc/yum.repos.d/*")
             . Util.stdexcl

  let xfm = transform lns filter
```

Augeas

Schema description

```
module Yum =
  autoload xfm

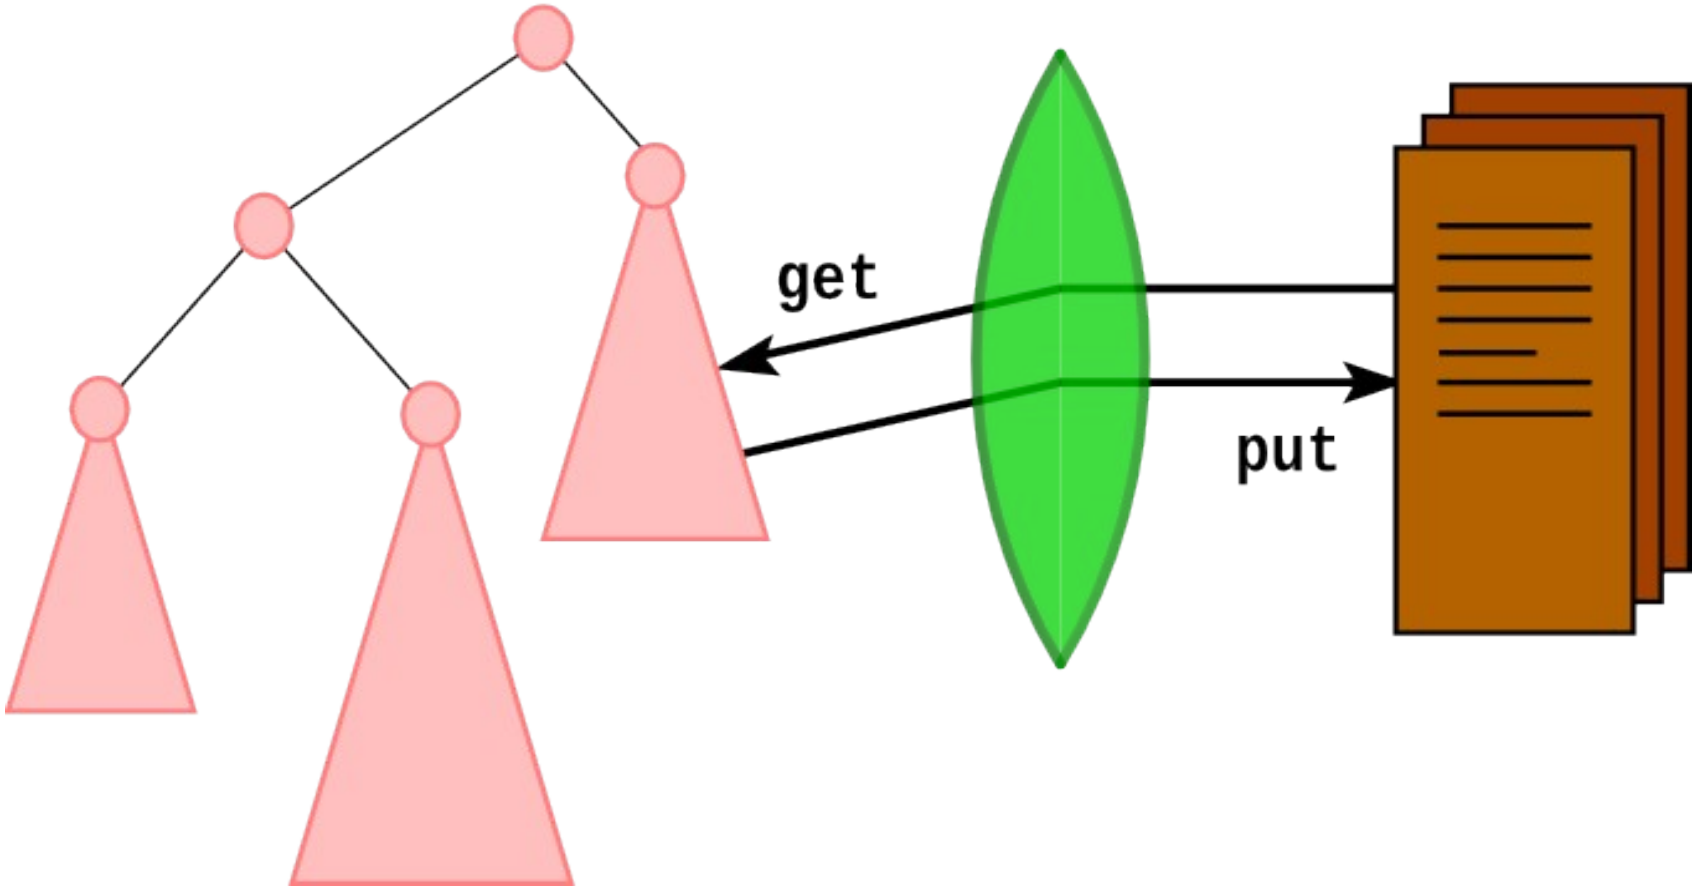
  let lns = ...

  let filter = (incl "/etc/yum.conf")
             . (incl "/etc/yum.repos.d/*")
             . Util.stdexcl

  let xfm = transform lns filter
```

Augeas

Lenses



Augeas

Lenses

Concrete View ↔ Abstract View

Bidirectional programming

Concrete ⟶ Abstract + Abstract ⟶ Concrete

- Harmony (U Penn) does it for trees
- Boomerang (U Penn) does it for strings
- Theoretical groundwork by B. Pierce, N. Foster et.al.

Augeas

Lenses for Augeas

String ↔ Tree

get: String ⟶ Tree

put: Tree x String ⟶ String

Lens Laws

The `get` and `put` of every lens must fulfill:

```
put (get c) c = c

get (put a c) = a
```

- Capture intuitive notions of “minimal” edits
- Constraints enforced by typechecker

Augeas

Lens primitives

- Tree labels
  - `key re`
  - `label str`
  - `seq str`
- Tree values
  - `store re`
- Omit from tree
  - `del re str`

Augeas

Lens combinators

- `l1 . l2` : Lens concatenation
- `l1 | l2` : Lens union
- `l*, l+` : Lens iteration
- `[ l ]` : Subtree combinator

Lens development

- Build up lenses from small parts
- Reuse common constructs
  - Comment goes from # to end of line
- Unit test facility in Augeas language
  - Run get direction
  - Run get direction, modify tree, run put direction
  - Compare to fixed value
  - Assert exception
  - Print result

Augeas

Lens development

Process “`key=value`”

Lens development

Process “key=value”

```
let eq = del “=” “=”
```

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]
```

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]
```

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]
```

Augeas

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]

test lns get “foo=bar” = ?
```

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]

test lns get “foo=bar” = { “foo” = “bar” }
```

Augeas

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]

test lns get “foo2=bar1” = *
```

Augeas

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns = [key /[a-z]+/ . eq . store /.+/ ]

test lns put “foo=bar”
         after set “foo” “baz”
         = ?
```

Augeas

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns = [key /[a-z]+/ . eq . store /.+/ ]

test lns put “foo=bar”
          after set “foo” “baz”
          = ?
```

Augeas

Lens development

Process “key=value”

```
let eq = del “=” “=”
let lns = [key /[a-z]+/ . eq . store /.+/ ]

test lns put “foo=bar”
          after set “foo” “baz”
          = “foo=baz”
```

Augeas

Lens development

Process “key=value”

```
let eq = del /[ \t]+=[ \t]+/ “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]
```

Augeas

Lens development

Process “key=value”

```
let eq = del /[ \t]+=[ \t]+/ “=”
let lns =[ key /[a-z]+/ . eq . store /.+/ ]
```

Lens development

Process “key=value”

```
let eq = del /[ \t]+=[ \t]+/ “=”
let lns =[ key /[a-z]+/ . eq . store /[a-z]+/ ]

test lns put “foo \t= bar”
          after set “foo” “baz”
          = “foo \t= baz”
```

Augeas

Arrays – using ***seq***

```
hosts/
  1/
    ipaddr
    canonical
    alias
    alias
  2/
    ipaddr
    canonical
    alias
```

Augeas

Arrays – using identical labels

```
hosts/
  1/
    ipaddr
    canonical
    alias
    alias
  2/
    ipaddr
    canonical
    alias
```

Augeas

Handling comments

```
let comment = del /#.*\n/ “#\n”

let lns = (record|comment)*
```

Handling comments

```
let comment = [ del /#.*\n/ "#\n" ]

let lns = (record|comment)*
```

The lens typechecker

- Each lens has associated *ctype* and *atype*
  - Regular languages

- Checks during lens construction
  - `del re str` : `str` must match `re`
  - `l1 . l2` : unambiguously splittable
  - `l1 | l2` : disjoint regular languages

- `libfa` for finite automata computations
- Restricts Augeas to regular file formats

Augeas

Supported file formats

/etc/hosts /etc/inittab yum config /etc/fstab /etc/exports

/etc/aliases /etc/ssh/sshd_config ntp

shell vars in /etc/sysconfig/ logrotate

ifcfg-*

apt preferences/sources dput pam.d

grub.conf xinetd.d vsftpd.conf

your contribution here

Augeas

What about `httpd.conf` ?

- Mostly tedious boilerplate
- Except:

```
...
   <IfModule mod_proxy.c>
      ...
   </IfModule>
...
```

- Arbitrary nesting, not regular
  - Need recursion + regular approximation

Augeas

A higher level service

Dbus service backed by Augeas

+

PolicyKit mechanism for authentication

=

Local configuration service

UI independent

File format independent

Fine grained permissioning

Harald Hoyer has prototype for `system-config-boot`

Supported platforms

- Red Hat Linux flavors
  - Fedora, RHEL, CentOS, ...
- Other Linux flavors
  - Debian
- FreeBSD
- OS/X port on the way

Minimal dependencies

- Anything with a GNU libc (or equivalent gnulib support)
